Python doesn't pre-package with Windows, but that doesn't mean Windows users won't find a flexible programming language useful. It's not quite as easy as installing the newest version however, so let's make sure you get the right tools for the task at hand. First released in 1991, Python is a popular high-level programming language used for general purpose programming. Thanks to a design philosophy that emphasizes readability, it has long been a favorite hobby of programmers and serious programmers. Not only is it a simple language (comparatively speaking, that is) to pick up, but you'll find thousands of projects online that require you to have a Python set to use the program. What version do you need? Unfortunately, a few years ago there was a significant update of Python, which created a big rift between versions of Python. This may make things a little confusing for beginners, but don't worry. We'll get you through installing both major versions. When you visit the Python Download Page for Windows, you'll immediately see the separation. Right at the top, square and center, the repository asks if you want the latest release of Python 2 or Python 3 (2.7.13 and 3.6.1, respectively, as of this tutorial). RELATED: Add dungeons, ruins, and treasure hunting to your Minecraft world with MCDungeon New Better, right? Maybe so, maybe not. The version you want depends on your goal. Let's say, for example, that you are reading our article about expanding your Minecraft world with MCDungeon and are happy to add interesting things to your worlds. This project is encoded in Python and requires Python 2.7 - you can't run the MCDungeon project with Python 3.6. In fact, if you are studying hobby projects like MCDungeon, you will find that almost all of them use 2.7. If your goal is to get some project that ends in .py extension and works, then there is a very, very good chance that you need 2.7 for it. On the other hand, if you want to actually learn Python, we recommend installing both versions side by side (which you can do with zero risk and just a tiny bit of installation hassle). This allows you to work with the latest version of the language, as well as run old Python scripts (and test backward compatibility for new projects). Comparing the two versions is an article in itself though, so we'll put it off on the Python Wiki project where you can read their well-written review of the differences. You can just download Python 2 or Python 3 if you're sure you only need a specific version. We go the distance today and will be installing both of them, so we recommend you download both versions and do the same. Under the main entry for both versions, you'll see the x86-64 installer, as shown below. What is the difference between 32-bit and 64-bit Windows? This installer will install a corresponding 32-bit or 64-bit version on computer automatically (here are some further readings if you want to learn more about the differences between them). Instructions Instructions Python 2 Installation Python 2 is a snap, and unlike past years, the installer even set the way of variable for you (something we'll get in a little later). Download and run the installer, select Set for all users, and then click next. On the catalog selection screen, leave the catalog as Python27 and click Next. On the customization screen, scroll down, click add python.exe to the path, and then select Will be mounted on your local hard drive. When you are done, click next. You don't have to make any more decisions after that moment. Just click through the master to complete the installation. When the installation is finished, you can confirm the installation by opening Command Prompt and typing the following command: python-V Success! If all you need is Python 2.7 for a project, you can stay right here. It is set, a variable path is set and you have gone to the race. How to install Python 3 If you want to know the newest version of Python, you need to install Python 3. You can install it along with Python 2.7 with no problem, so go ahead and download and run the installer now. On the first screen, turn on the Add Python 3.6 option to PATH, and then click set now. Next, you have to make a decision. Clicking the Limiting The Length of the Triple removes the MAX_PATH variable limit. This change won't break anything, but will allow Python to use the names of long trajectories. Because many Python programmers work in Linux and other nix systems where the length of the path name is not a problem, including this in advance can help mitigate any trajectory problems that may occur while working in Windows. ANSWER: How to make Windows 10 Take File Ways over 260 characters We recommend going ahead and choosing this option. If you know you don't want to unplug the length limit, you can just press the Close button to finish the installation. And, if you want to know more about the problem before making changes, read here. If you only install Python 3, you can use the same command line trick entering python-v that we used above to check that it is set correctly and the variable path is set. If you install both versions, however, you need to do a quick setup to find in the next section. Adjust system variables so you can access both python versions from the command line This section of the tutorial is completely optional, but will allow you to quickly access both versions of Python from the command line. After installing both versions of Python, you may have noticed a small quirk. Although we've included a system path for both Python installations, the python input in the command hint indicates only Python 2.7. The reason for this is simple: variable (whether automatically adjusted by the installer or set up) simply points to the catalog, and each directory in this directory becomes a command line team. If you list two directories and have a python.exe file in them, depending on the catalog above in the list of variables gets used. And, if there is a variable set for the system and the user, the way the system takes precedence over the user path. The latter is exactly what happens in this case: The Python 2 installer edited the system to a broad variable and the Python 3 installer added a variable user level, and we can confirm this by looking at the variable Windows environments. Hit Start, enter advanced system settings, and then select the Option View Advanced System Settings. In the System Properties window, which opens in the Advanced tab, click the Environmental Variable button. Here you can see the Python 3 listed in the User Variables and Python 2 section listed in the System Variables section. There are several ways you can fix this situation. The easiest (albeit with the least functionality) is to simply delete the entry for the Python version you plan to use the least. Although it's simple, it's also not much fun. Instead, we can make another change that will give us access to the python for Python 2 and python3 for Python 3. To do this, head to the file manager and go to the folder where you installed Python 3 (C: Users username\AppData\Local\programs\Python\Python36 by default). Make a copy of the python.exe file and rename this copy (not the original) in python3.exe. Open a new team query (environmental variables are updated with each new team, tells you to open) and in the air python3 -version. Boom! Now you can use the python command in Command Prompt when you want to use Python 2.7 and the python3 command when you want to use Python 3. ANSWER: How to edit the PATH system for easy command line access in Windows If, for whatever reason, you don't find this satisfactory solution, you can always change the order of environmental variables. Be sure to brush up with our tutorial first if you're not comfortable editing these variables. Note, however, that no matter what method you use, it is important to leave the original python.exe intact because applications in /scripts/sub-direction for both versions of Python rely on that file name and fail if it is not available. After a little setup and a little tweaking, you have both versions installed and you're ready for any Python project you want to tackle. Today I'll show you how to make a simple ghost game in a python. I assume you have a python, if not, click here. Scroll down and look for python 3. The room should have three ahead, but the others don't matter. Then open IDLE (python GUI), open a new file and save it as a ghost game or something. All shown above Note: This is from the book, I'm just showing you how to do it on instructables. Copy in this to the window:#Ghost Game (not necessarily) from import randint print ('Ghost Game') feeling_brave = True score = 0 hit F5 or run in running and play your game. I hope you enjoyed it instructable! Instructable! python programming on win32 download pdf door_num int (door)Go to:door_num and ghost_door:print ('GHOST!!!!') feeling_brave = False else:print ('No to the Ghost!') print ('you enter the next room')score = 1Type:print ('Run! Seal (you scored', score)Save, hit F5 or run in running and play your game.
